

**SINGLE KU-BAND MULTI-POLARIZATION GALLIUM ARSENIDE
TRANSMIT CHIP**

Related Applications

This application is a divisional of ^{pending} U.S. application serial
Field of the Invention no. 10/014,553 filed on 14 December 2001.

The present invention generally relates to a multi-polarization active array
transmit antenna.

Background of the Invention

- 5 Array transmit antenna technology is widely used in the area of satellite
telecommunication, data transmission, radar systems and voice communication systems.
Array antennas use electronic scanning technologies, such as time delay scanning,
frequency scanning, or phase scanning to steer the transmitted beam. Use of electronic
scanning allows an antenna system to achieve increased transmission data rates,
10 instantaneous beam positioning, and the ability to operate in a multi-target mode. By
using electronic scanning technology, an array transmit antenna can perform multiple
functions that are otherwise performed by several separate antenna systems. Of the
several electronic scanning technologies, phase scanning is the one used most widely in
array antennas. Phase scanning is based on the principle that electro-magnetic energy
15 received at a point in space from two or more closely-spaced radiating elements is at a
maximum when the energy from each radiating element arrives at that point in phase. An
array transmit antenna using the phase scanning technique is known as a "phased array
antenna."
